# Introductory Thoughts

This is introductory material.

## Lecture 2

# Gaussian Integrals

## 2.1 Multidimensional Gaussian Integrals

Consider the  $n$ -dimensional integral

$$Z_A = \int d^n x \exp \left( -\frac{1}{2} \sum_{i,j=1}^n x_i A_{ij} x_j \right). \quad (2.1)$$

If  $A$  is a complex, symmetric  $n \times n$  matrix such that

$$\operatorname{Re} A \geq 0, \quad (2.2)$$

$$a_i \neq 0, \quad a_i \text{ e.vals of } A, \quad (2.3)$$

then

$$Z_A = (2\pi)^{n/2} (\det A)^{-1/2}. \quad (2.4)$$

### General Gaussian Integral

$$Z_A(b) = \int d^n x \exp \left( -\frac{1}{2} \sum_{i,j=1}^n x_i A_{ij} x_j + \sum_{i=1}^n b_i x_i \right) \quad (2.5)$$

$$= (2\pi)^{n/2} (\det A)^{-1/2} \exp \left( \frac{1}{2} \sum_{i,j=1}^n b_i \Delta_{ij} b_j \right), \quad (2.6)$$

where  $\Delta = A^{-1}$ . The existence of  $\Delta$  is guaranteed by the non-vanishing e.vals of  $A$ .

**Exercise 2.1.1** Check the result in Eq. 2.6 by changing the integration variables in the integral:

$$x_i = y_i + \sum_{j=1}^n \Delta_{ij} b_j.$$

## 2.2 Generating function

Let  $\mu$  be a measure in  $\mathbb{R}^n$ , we define the expectation value

$$\langle F \rangle_\mu = \int d\mu(x) F(x) \quad (2.7)$$

$$= \int d^n x \Omega(x) F(x). \quad (2.8)$$

The measure is normalised so that

$$\int d\mu(x) = 1. \quad (2.9)$$

We define the generating function

$$Z_\mu(b) = \langle e^{(b,x)} \rangle_\mu = \int d\mu(x) \exp \left( \sum_{i=1}^n b_i x_i \right). \quad (2.10)$$

The notation emphasises that  $Z_\mu$  is a function of the  $n$ -dimensional vector  $b$ . The dependence on the integration measure that defines the expectation value is indicated by the suffix  $\mu$ . Note that we introduced the notation  $(.,.)$  to denote the scalar product of two vectors in  $\mathbb{R}^n$ .

The integrand can be expanded

$$\exp \left( \sum_{i=1}^n b_i x_i \right) = \sum_{\ell=0}^{\infty} \frac{1}{\ell!} \left( \sum_{i=1}^n b_i x_i \right)^\ell \quad (2.11)$$

$$= \sum_{\ell=0}^{\infty} \frac{1}{\ell!} \sum_{i_1 \dots i_\ell=1}^n b_{i_1} \dots b_{i_\ell} x_{i_1} \dots x_{i_\ell}. \quad (2.12)$$

Therefore

$$Z_\mu(b) = \sum_{\ell=0}^{\infty} \frac{1}{\ell!} \sum_{i_1 \dots i_\ell=1}^n b_{i_1} \dots b_{i_\ell} \langle x_{i_1} \dots x_{i_\ell} \rangle_\mu, \quad (2.13)$$

where

$$\langle x_{i_1} \dots x_{i_\ell} \rangle_\mu = \int d\mu(x) x_{i_1} \dots x_{i_\ell} \quad (2.14)$$

are called correlation functions of the variable  $x$  in the measure  $\mu$ .

It is useful to notice that

$$\frac{\partial}{\partial b_k} Z_\mu(b) = \int d\mu(x) x_k \exp \left( \sum_{i=1}^n b_i x_i \right), \quad (2.15)$$

which allows the correlators above to be written as

$$\langle x_{i_1} \dots x_{i_\ell} \rangle_\mu = \frac{\partial}{\partial b_{i_1}} \dots \frac{\partial}{\partial b_{i_\ell}} Z_\mu(b) \Big|_{b=0}. \quad (2.16)$$

## 2.3 Generating Function and Gaussian Integrals

Let us consider the Gaussian measure

$$d\mu_0(x) = d^n x \Omega_0(x) = d^n x \mathcal{N}_0 \exp \left( -\frac{1}{2} \sum_{i,j=1}^n x_i A_{ij} x_j \right), \quad (2.17)$$

where the normalization  $\mathcal{N}_0$  is fixed by Eq. 2.9

$$\mathcal{N}_0 = (2\pi)^{-n/2} (\det A)^{1/2} . \quad (2.18)$$

**Exercise 2.3.1** Check that  $\mathcal{N}_0 = Z_A^{-1}$  yields the correct normalization.

The generating function in this case can be readily computed using Eq. 2.6:

$$Z_0(b) = \frac{Z_A(b)}{Z_A} = \exp \left( \frac{1}{2} \sum_{i,j=1}^n b_i \Delta_{ij} b_j \right) . \quad (2.19)$$

And therefore

$$\langle x_{i_1} \dots x_{i_\ell} \rangle_0 = \frac{\partial}{\partial b_{i_1}} \dots \frac{\partial}{\partial b_{i_\ell}} \exp \left( \frac{1}{2} \sum_{i,j=1}^n b_i \Delta_{ij} b_j \right) \Big|_{b=0} , \quad (2.20)$$

where the suffix '0' on the LHS is a reminder that the expectation value is computed for the Gaussian measure in Eq. 2.17. Eq. 2.20 allows us to define the expectation value for any function  $F(x)$  that admits a Taylor expansion,

$$F(x) = \sum_{i_1 \dots i_\ell=1}^n F_{i_1, \dots, i_\ell} x_{i_1} \dots x_{i_\ell} . \quad (2.21)$$

The expectation value of  $F$  for a generic measure  $\mu$  is defined as

$$\langle F(x) \rangle_\mu = \sum_{\ell=0}^{\infty} \sum_{i_1 \dots i_\ell=1}^n F_{i_1, \dots, i_\ell} \langle x_{i_1} \dots x_{i_\ell} \rangle_\mu ; \quad (2.22)$$

and for the case of a Gaussian measure we obtain

$$\langle F(x) \rangle_0 = \sum_{\ell=0}^{\infty} \sum_{i_1 \dots i_\ell=1}^n F_{i_1, \dots, i_\ell} \frac{\partial}{\partial b_{i_1}} \dots \frac{\partial}{\partial b_{i_\ell}} \exp \left( \frac{1}{2} \sum_{i,j=1}^n b_i \Delta_{ij} b_j \right) \Big|_{b=0} \quad (2.23)$$

$$= F \left( \frac{\partial}{\partial b} \right) \exp \left( \frac{1}{2} \sum_{i,j=1}^n b_i \Delta_{ij} b_j \right) \Big|_{b=0} , \quad (2.24)$$

where the differential operator  $F(\partial/\partial b)$  is defined by the Taylor expansion

$$F \left( \frac{\partial}{\partial b} \right) = \sum_{\ell=0}^{\infty} \sum_{i_1 \dots i_\ell=1}^n F_{i_1, \dots, i_\ell} \frac{\partial}{\partial b_{i_1}} \dots \frac{\partial}{\partial b_{i_\ell}} . \quad (2.25)$$

## 2.4 Gaussian Correlators: Wick's Theorem

Eq. 2.20 allows us to compute all Gaussian correlators. It is instructive to start with a couple of explicit examples, which we will compute in full detail in order to get familiar with the algebraic manipulations.

**One-point function** Let  $k$  be an integer between 1 and  $n$ , we have

$$\langle x_k \rangle_0 = \frac{\partial}{\partial b_k} \exp \left( \frac{1}{2} \sum_{i,j=1}^n b_i \Delta_{ij} b_j \right) \Big|_{b=0} \quad (2.26)$$

$$= \left( \frac{1}{2} \sum_{j=1}^n \Delta_{kj} b_j + \frac{1}{2} \sum_{i=1}^n b_i \Delta_{ik} \right) \exp \left( \frac{1}{2} \sum_{i,j=1}^n b_i \Delta_{ij} b_j \right) \Big|_{b=0} \quad (2.27)$$

$$= \left( \sum_{j=1}^n \Delta_{kj} b_j \right) \exp \left( \frac{1}{2} \sum_{i,j=1}^n b_i \Delta_{ij} b_j \right) \Big|_{b=0} \quad (2.28)$$

$$= 0, \quad (2.29)$$

where the last equality comes from the fact that the expression is linear in  $b$ , and we need to set  $b = 0$ .

**Exercise 2.4.1** Check the calculation above in **full** detail. The result is expected, can you figure out why?

**Two-point function** We now consider a pair of indices  $k, l$ , and compute

$$\langle x_k x_l \rangle_0 = \frac{\partial}{\partial b_l} \frac{\partial}{\partial b_k} \exp \left( \frac{1}{2} \sum_{i,j=1}^n b_i \Delta_{ij} b_j \right) \Big|_{b=0}. \quad (2.30)$$

Starting from Eq. 2.28, we can easily derive

$$\langle x_k x_l \rangle_0 = \left\{ \Delta_{kl} \exp \left( \frac{1}{2} \sum_{i,j=1}^n b_i \Delta_{ij} b_j \right) \right. \quad (2.31)$$

$$\left. + \left( \sum_{j=1}^n \Delta_{kj} b_j \right) \left( \sum_{m=1}^n \Delta_{lm} b_m \right) \exp \left( \frac{1}{2} \sum_{i,j=1}^n b_i \Delta_{ij} b_j \right) \right\} \Big|_{b=0} \quad (2.32)$$

$$= \left[ \Delta_{kl} + \left( \sum_{j=1}^n \Delta_{kj} b_j \right) \left( \sum_{m=1}^n \Delta_{lm} b_m \right) \right] \exp \left( \frac{1}{2} \sum_{i,j=1}^n b_i \Delta_{ij} b_j \right) \Big|_{b=0} \quad (2.33)$$

$$= \Delta_{kl}, \quad (2.34)$$

where again the simplification in the last line occurs because the vector  $b$  is set to zero. We have obtained from the generating function a result that you may have seen already:

$$\langle x_k x_l \rangle_0 = \mathcal{N}_0 \int d^n x \exp \left( -\frac{1}{2} \sum_{i,j=1}^n x_i A_{ij} x_j \right) x_k x_l \quad (2.35)$$

$$= A_{kl}^{-1}. \quad (2.36)$$

For the case of  $n = 1$ , the latter simplifies to the familiar formula

$$\langle x^2 \rangle_0 = \mathcal{N}_0 \int dx e^{-x^2/(2\sigma^2)} x^2 = \sigma^2. \quad (2.37)$$

The generating function  $Z_0(b)$  provides a systematic way to compute all correlators for a multi-dimensional Gaussian distribution.

**General Case** Having seen two examples in detail, we can try to understand the general pattern that appears when taking derivatives of the Gaussian generating function. The generating function is the exponential of a bilinear in the vector  $b$ . A derivative with respect to  $b_k$  acting on the exponential 'brings down' a term that is linear in  $b$  and multiplies the exponential. Some other derivative, e.g. with respect to  $b_l$ , *must* act on this factor, otherwise the contribution is proportional to  $b$  and vanishes when we set  $b = 0$  in the final step of the computation - cfr. the terms that vanish in the two explicit computations discussed above. When the second derivative acts on the linear term a term  $\Delta_{kl}$  is generated, and survives when  $b = 0$ . Hence we obtain the following recipe to compute  $\langle x_{i_1} \dots x_{i_\ell} \rangle_0$ :

- Write *all* the possible pairings  $(i_p, i_q)$  of the indices  $i_1, \dots, i_\ell$ . Note in this step that  $\ell$  must be even, otherwise the correlator vanishes!

- Denote by  $P$  the set of all pairings  $\{(P_1, P_2), \dots, (P_{\ell-1}, P_\ell)\}$ , where  $P_1, \dots, P_\ell$  is a permutation of the indices  $i_1, \dots, i_\ell$ .
- To each pair  $(P_i, P_j)$  associate a factor  $\Delta_{P_i, P_j}$ .

So finally

$$\langle x_{i_1} \dots x_{i_\ell} \rangle_0 = \sum_P \langle x_{P_1} x_{P_2} \rangle_0 \dots \langle x_{P_{\ell-1}} x_{P_\ell} \rangle_0 \quad (2.38)$$

$$= \sum_P \Delta_{P_1 P_2} \dots \Delta_{P_{\ell-1} P_\ell}. \quad (2.39)$$

This results is known as Wick's theorem. Let us now see how Wick's theorem is applied in some simple examples.

**Two-point function revisited** We need to compute  $\langle x_{i_1} x_{i_2} \rangle_0$ . In this case there are two indices and therefore only *one* possible pairing,  $(i_1, i_2)$ . The set  $P$  of all pairings consists of just the one pair, and therefore

$$\langle x_{i_1} x_{i_2} \rangle_0 = \Delta_{i_1 i_2}. \quad (2.40)$$

**Four-point function** We can now compute the four-point correlator  $\langle x_{i_1} x_{i_2} x_{i_3} x_{i_4} \rangle_0$ . First we need to identify the pairings; in this case there are *three* different ones

$$P = \{ \{(i_1, i_2), (i_3, i_4)\}, \{(i_1, i_3), (i_2, i_4)\}, \{(i_1, i_4), (i_2, i_3)\}, \} . \quad (2.41)$$

Wick's theorem then yields

$$\langle x_{i_1} x_{i_2} x_{i_3} x_{i_4} \rangle_0 = \Delta_{i_1 i_2} \Delta_{i_3 i_4} + \Delta_{i_1 i_3} \Delta_{i_2 i_4} + \Delta_{i_1 i_4} \Delta_{i_2 i_3}. \quad (2.42)$$

We can represent this result pictorially as

$$\langle x_{i_1} x_{i_2} x_{i_3} x_{i_4} \rangle_0 = \overbrace{x_{i_1} x_{i_2} x_{i_3} x_{i_4}} + \overbrace{x_{i_1} x_{i_2} x_{i_3} x_{i_4}} + \overbrace{x_{i_1} x_{i_2} x_{i_3} x_{i_4}}. \quad (2.43)$$

The equation above allows you to visualise clearly the three possible pairings. Every *Wick contraction* yields a factor of  $\Delta$ :

$$\langle x_i x_j \rangle_0 = \overbrace{x_i x_j} = \Delta_{ij}. \quad (2.44)$$

**Number of Pairings** We have seen enough examples now to be able to estimate the number of pairings that will appear when computing an  $\ell$ -point correlator  $\langle x_{i_1} \dots x_{i_\ell} \rangle_0$ . First of all, remember that  $\ell$  has to be even, and therefore we can write  $\ell = 2p$ , where  $p$  is an integer. Then

$$\# \text{ of pairings} = (2p - 1) \times (2p - 3) \dots 3 \times 1. \quad (2.45)$$

You can check that this formula reproduces the right results for  $\ell = 2, 4$ .

**Six-point function** For the case of a six-point function,  $\ell = 6$ ,  $p = 3$ , and hence

$$\# \text{ of pairings} = 5 \times 3 \times 1 = 15. \quad (2.46)$$

**Exercise 2.4.2** Try listing all the possible pairings, and write the result for the six-point function using Wick's theorem.

**Exercise 2.4.3**

$$\langle x_k F(x) \rangle_0 = \int d\mu_0(x) x_k F(x) \quad (2.47)$$

Show that

$$\langle x_k F(x) \rangle_0 = \sum_l \langle x_k x_l \rangle_0 \left\langle \frac{\partial F}{\partial x_l} \right\rangle_0. \quad (2.48)$$

*Hint:*

$$-\sum_l \Delta_{kl} \frac{\partial}{\partial x_l} \exp \left( -\frac{1}{2} \sum_{i,j=1}^n x_i A_{ij} x_j \right) = x_k \exp \left( -\frac{1}{2} \sum_{i,j=1}^n x_i A_{ij} x_j \right). \quad (2.49)$$

## 2.5 Perturbed Gaussian Measure

Let us consider now a more complicated measure,

$$\Omega(x) = \frac{1}{Z(\lambda)} e^{-S(x,\lambda)}, \quad (2.50)$$

where the normalization is given as usual by

$$Z(\lambda) = \int d^n x e^{-S(x,\lambda)}, \quad (2.51)$$

and

$$S(x, \lambda) = \frac{1}{2} \sum_{i,j=1}^n x_i A_{ij} x_j + \lambda V(x) \quad (2.52)$$

$$= S_0(x) + \lambda V(x), \quad (2.53)$$

where we have introduced  $S_0$  to denote the Gaussian part of the measure that we have already discussed in the sections above. The term proportional to  $\lambda$  in  $S$ , which we will call the potential term, describes the deviation from gaussianity.  $Z(\lambda)$  can be computed by expanding the exponential of the potential and using the results of the previous section.

$$Z(\lambda) = \sum_{k=0}^{\infty} \frac{(-\lambda)^k}{k!} \int d^n x V(x)^k \exp \left( -\frac{1}{2} \sum_{i,j=1}^n x_i A_{ij} x_j \right) \quad (2.54)$$

$$= Z(0) \sum_{k=0}^{\infty} \frac{(-\lambda)^k}{k!} \langle V(x)^k \rangle_0, \quad (2.55)$$

where the expectation value in the last line is a Gaussian average of the kind we have discussed in the previous section.

Using Eq. 2.24

$$\frac{Z(\lambda)}{Z(0)} = \langle e^{-\lambda V(x)} \rangle_0 \quad (2.56)$$

$$= \exp \left[ -\lambda V \left( \frac{\partial}{\partial b} \right) \right] \exp \left( \frac{1}{2} \sum_{i,j=1}^n b_i \Delta_{ij} b_j \right) \bigg|_{b=0}. \quad (2.57)$$

**Exercise 2.5.1** Compute the ratio

$$Z(\lambda)/Z(0) \quad (2.58)$$

for the potential

$$V(x) = \frac{1}{4!} \sum_{i=1}^n x_i^4, \quad (2.59)$$

to second order in  $\lambda$ .

**This exercise is very important. Make sure you understand all the steps in full detail.**

**Solution**

$$Z(\lambda)/Z(0) = 1 - \frac{1}{4!} \lambda \sum_{i=1}^n \langle x_i^4 \rangle_0 + \frac{1}{2!} \frac{1}{(4!)^2} \lambda^2 \sum_{i,j=1}^n \langle x_i^4 x_j^4 \rangle_0 + O(\lambda^3) \quad (2.60)$$

$$= 1 - \frac{\lambda}{8} \sum_{i=1}^n \Delta_{ii}^2 + \lambda^2 \left[ \frac{1}{128} \sum_i \Delta_{ii}^2 \sum_j \Delta_{jj}^2 + \frac{1}{16} \sum_{ij} \Delta_{ii} \Delta_{jj} \Delta_{ij}^2 + \frac{1}{48} \sum_{ij} \Delta_{ij}^4 \right] + O(\lambda^3). \quad (2.61)$$

You can check that for  $n = 1$  you recover the well-known result

$$Z(\lambda)/Z(0) = 1 - \frac{1}{8} \lambda + \frac{35}{184} \lambda^2 + O(\lambda^3). \quad (2.62)$$

**Diagrammatic representation** We can introduce a convenient diagrammatic representation for the expression above. To each factor  $\Delta_{ij}$ , we associate a line with indices  $i$  and  $j$  at its ends:

$$\Delta_{ij} = \text{---} \underset{i}{\text{---}} \underset{j}{\text{---}}. \quad (2.63)$$

Whenever the end of a line is part of a closed path, we sum over the corresponding index, so for instance:

$$\text{---} \underset{i}{\text{---}} \text{---} \text{---} \text{---} \text{---} \underset{i}{\text{---}} = \sum_{i=1}^n \Delta_{ii}, \quad (2.64)$$

$$\text{---} \underset{i}{\text{---}} \text{---} \text{---} \text{---} \text{---} \underset{j}{\text{---}} \text{---} \text{---} \text{---} \underset{j}{\text{---}} = \sum_{j=1}^n \Delta_{ij} \Delta_{jj}. \quad (2.65)$$

Using this notation, we can rewrite Eq. 2.60

$$\begin{aligned}
 Z(\lambda)/Z(0) = & 1 - \lambda \left[ \frac{1}{8} \text{ (loop at } i \text{)} \right] + \\
 & + \lambda^2 \left[ \frac{1}{128} \text{ (two loops at } i \text{ and } j \text{)} + \frac{1}{16} \text{ (figure-eight at } i \text{ and } j \text{)} + \frac{1}{48} \text{ (two loops at } i \text{ and } j \text{)} \right]. \quad (2.66)
 \end{aligned}$$

It is clear from the diagrammatic representation that we can distinguish connected and disconnected contributions. The connected contributions are represented by connected diagrams, i.e. diagrams that are made of a single line. The disconnected diagrams are products of multiple connected parts, and therefore correspond to products of independent sums over subset of indices. In Eq. 2.60 only the first term in the bracket in the second line is a disconnected contribution.

**Connected contribution** Using the Taylor expansion for the logarithm,

$$\log(1+x) = \sum_{n=1}^{\infty} (-1)^{n+1} \frac{x^n}{n}, \quad (2.67)$$

we can compute

$$\begin{aligned}
 \log(Z(\lambda)/Z(0)) = & -\lambda \frac{1}{8} \sum_{i=1}^n \Delta_{ii}^2 + \\
 & + \lambda^2 \left[ \frac{1}{128} \sum_i \Delta_{ii}^2 \sum_j \Delta_{jj}^2 + \frac{1}{16} \sum_{ij} \Delta_{ii} \Delta_{jj} \Delta_{ij}^2 + \frac{1}{48} \sum_{ij} \Delta_{ij}^4 \right] - \\
 & - \lambda^2 \frac{1}{2} \left( -\frac{1}{8} \sum_{i=1}^n \Delta_{ii}^2 \right)^2 + O(\lambda^3). \quad (2.68)
 \end{aligned}$$

Eq. 2.68 shows explicitly the cancellation at order  $\lambda^2$  between the first term in the square bracket in the second line, and the last term in the third line, which comes from squaring the order  $\lambda$  contribution when computing the second term in the Taylor expansion in Eq. 2.67. This is a general property, taking the logarithm of the generating function yields the generating function of connected contributions. We shall prove this property later in the course.

## 2.6 Perturbed Gaussian Correlators

The perturbative treatment discussed above can be extended to compute moments of the distribution:

$$\langle x_{i_1} \dots x_{i_\ell} \rangle = \frac{1}{Z(\lambda)} \int d^n x e^{-S(x;\lambda)} x_{i_1} \dots x_{i_\ell}, \quad (2.69)$$

which often referred to as an  $\ell$ -point correlator/function. Let us start our discussion with a simple example.

**Two-point function** We need to evaluate

$$\int d^n x e^{-S(x;\lambda)} x_{i_1} x_{i_2} = \int d^n x e^{-S_0(x;\lambda)} \left[ \sum_{k=0}^{\infty} \frac{(-)^k}{k!} \lambda^k V(x)^k \right] x_{i_1} x_{i_2} \quad (2.70)$$

$$= Z(0) \sum_{k=0}^{\infty} \frac{(-)^k}{k!} \lambda^k \langle V(x)^k x_{i_1} x_{i_2} \rangle_0, \quad (2.71)$$

where in the second line we have expressed the initial correlator in terms of correlators computed in the Gaussian theory, denoted as before by  $\langle \dots \rangle_0$ . The Gaussian correlators can be computed using Wick's theorem as before. We shall consider again a quartic potential:

$$V(x) = \frac{1}{4!} \sum_{i=1}^n x_i^4, \quad (2.72)$$

and compute all the terms in Eq. 2.71 order by order in  $\lambda$  up to order  $\lambda^2$ .

- $O(\lambda^0)$  For  $k = 0$  we simply get the two-point Gaussian correlator:

$$\langle x_{i_1} x_{i_2} \rangle_0 = \Delta_{i_1 i_2}. \quad (2.73)$$

- $O(\lambda^1)$  At first order in  $\lambda$  we have one insertion of  $V$ :

$$\langle V(x) x_{i_1} x_{i_2} \rangle_0 = \frac{1}{4!} \sum_{i=1}^n \langle x_i^4 x_{i_1} x_{i_2} \rangle_0. \quad (2.74)$$

This Gaussian expectation value involving six factors of  $x$  (four from the potential, and the two coming from the fact that we compute a two-point function) can be evaluated using Wick's theorem. There two types of contractions.

- (i)  $x_1$  is contracted with  $x_2$ , and the four  $x_i$  are contracted amongst themselves:

$$\overbrace{x_{i_1} x_{i_2}} \left( \overbrace{x_i x_i x_i x_i} + \overbrace{x_i x_i x_i x_i} + \overbrace{x_i x_i x_i x_i} \right) = \Delta_{i_1 i_2} \langle x_i^4 \rangle_0, \quad (2.75)$$

where we have used the fact that the term inside the bracket on the LHS is simply  $\langle x_i^4 \rangle_0$  – cfr. Eq. 2.43.

- (ii)  $x_1$  and  $x_2$  are contracted with some of the  $x_i$ ; there are 12 such contractions:

$$\overbrace{x_{i_1} x_{i_2} x_i x_i x_i x_i} + \dots = \Delta_{ii_1} \Delta_{ii_2} \Delta_{ii} \times 4 \times 3. \quad (2.76)$$

Collecting all terms yields

$$\frac{1}{4!} \sum_{i=1}^n \langle x_i^4 x_{i_1} x_{i_2} \rangle_0 = \Delta_{i_1 i_2} \frac{1}{4!} \sum_{i=1}^n \langle x_i^4 \rangle_0 + \frac{1}{4!} \times 4 \times 3 \sum_{i=1}^n \Delta_{ii_1} \Delta_{ii_2} \Delta_{ii}. \quad (2.77)$$

- $O(\lambda^2)$  At this order we need to evaluate

$$\frac{1}{2!} \langle V(x)^2 x_{i_1} x_{i_2} \rangle_0 = \frac{1}{2!} \frac{1}{(4!)^2} \sum_{i,j=1}^n \langle x_i^4 x_j^4 x_{i_1} x_{i_2} \rangle_0. \quad (2.78)$$

There are five different types of contractions, each of them coming with a given multiplicity. We encourage the interested reader to compute those contributions, and check carefully that the correct multiplicities are recovered.

Collecting all contributions yields

$$\begin{aligned} \int d^n x e^{-S(x;\lambda)} x_{i_1} x_{i_2} &= Z(0) \left[ \Delta_{i_1 i_2} - \lambda \left( \Delta_{i_1 i_2} \frac{1}{4!} \sum_{i=1}^n \langle x_i^4 \rangle_0 + \frac{1}{2} \sum_{i=1}^n \Delta_{ii_1} \Delta_{ii_2} \Delta_{ii} \right) + \right. \\ &\quad + \lambda^2 \left( \frac{1}{2!} \Delta_{i_1 i_2} \frac{1}{(4!)^2} \sum_{i,j=1}^n \langle x_i^4 x_j^4 \rangle_0 + \frac{1}{2!} \sum_{i=1}^n \Delta_{ii_1} \Delta_{ii_2} \Delta_{ii} \frac{1}{4!} \sum_{j=1}^n \langle x_j^4 \rangle_0 + \right. \\ &\quad + \frac{1}{4} \sum_{i,j=1}^n \Delta_{ii_1} \Delta_{ii_2} \Delta_{ij}^2 \Delta_{jj} + \frac{1}{6} \sum_{i,j=1}^n \Delta_{ii_1} \Delta_{ji_2} \Delta_{ij}^3 + \\ &\quad \left. \left. + \frac{1}{4} \sum_{i,j=1}^n \Delta_{ii_1} \Delta_{ji_2} \Delta_{ij} \Delta_{ii} \Delta_{jj} \right) \right]. \quad (2.79) \end{aligned}$$

Diagrammatically we have:

$$\langle x_{i_1} x_{i_2} \rangle = \frac{Z(0)}{Z(\lambda)} \left[ \text{---}_{i_1} \text{---}_{i_2} + \frac{\lambda}{8} \text{---}_{i_1} \overset{\text{loop}}{\underset{i}{\text{---}}} \text{---}_{i_2} + \frac{\lambda}{2} \text{---}_{i_1} \overset{\text{vacuum loop}}{\underset{i}{\text{---}}} \text{---}_{i_2} + O(\lambda^2) \right], \quad (2.80)$$

where for simplicity we have omitted the contribution of order  $\lambda^2$ . A diagram that can be factorised as the product of a subdiagram with external lines and a subdiagram that is made of loops only is called a *vacuum contribution*. For instance the second diagram inside the bracket in Eq. 2.80 is a vacuum contribution, while the first and third ones are not.

Finally, we need to divide this expression by  $Z(\lambda)$  in order to obtain the two-point correlator as defined in Eq. 2.69. As a result, we obtain a factor of  $Z(0)/Z(\lambda)$  multiplying the expression inside the square bracket in Eq. 2.79. Inverting Eq. 2.60 for the ratio  $Z(0)/Z(\lambda)$  yields

$$Z(0)/Z(\lambda) = 1 + \frac{1}{4!} \lambda \sum_{i=1}^n \langle x_i^4 \rangle_0 - \frac{1}{2!} \frac{1}{(4!)^2} \lambda^2 \sum_{i,j=1}^n \langle x_i^4 x_j^4 \rangle_0 + \frac{1}{(4!)^2} \lambda^2 \left( \sum_{i=1}^n \langle x_i^4 \rangle_0 \right)^2 + O(\lambda^3) \quad (2.81)$$

**Exercise 2.6.1** Show that all the vacuum contributions cancel when computing  $\langle x_{i_1} x_{i_2} \rangle$ . The final result is

$$\begin{aligned} \int d^n x e^{-S(x;\lambda)} x_{i_1} x_{i_2} = Z(0) & \left[ \Delta_{i_1 i_2} - \lambda \frac{1}{2} \sum_{i=1}^n \Delta_{i i_1} \Delta_{i i_2} \Delta_{i i} + \right. \\ & + \lambda^2 \left( \frac{1}{4} \sum_{i,j=1}^n \Delta_{i i_1} \Delta_{i i_2} \Delta_{i j}^2 \Delta_{j j} + \frac{1}{6} \sum_{i,j=1}^n \Delta_{i i_1} \Delta_{j i_2} \Delta_{i j}^3 + \right. \\ & \left. \left. + \frac{1}{4} \sum_{i,j=1}^n \Delta_{i i_1} \Delta_{j i_2} \Delta_{i j} \Delta_{i i} \Delta_{j j} \right) \right]. \end{aligned} \quad (2.82)$$

Write a diagrammatic representation for the contributions  $O(\lambda^2)$ .

This is a general property: when the integral is divided by the correct normalization factor  $1/Z(\lambda)$ , all vacuum contributions cancel.

## 2.7 Generating Functions for the Perturbed Gaussian Measure

**Correlators** We can now generalise the idea of a generating function to the case of a non Gaussian measure. Introducing

$$Z(b; \lambda) = \int d^n x \exp [-S(x; \lambda) + (b, x)] , \quad (2.83)$$

where we introduced the notation

$$(b, x) = \sum_{i=1}^n b_i x_i . \quad (2.84)$$

Note that we can also write

$$\langle e^{(b, x)} \rangle = Z(b; \lambda) / Z(\lambda) . \quad (2.85)$$

The correlators in the perturbed measure are obtained by differentiation

$$\langle x_{i_1} \dots x_{i_\ell} \rangle = \frac{1}{Z(\lambda)} \frac{\partial}{\partial b_{i_1}} \dots \frac{\partial}{\partial b_{i_\ell}} Z(b; \lambda) \Big|_{b=0} . \quad (2.86)$$

**Cumulants** The logarithm of  $Z(b; \lambda)$  is usually denoted  $W(b; \lambda)$ ,

$$Z(b; \lambda) = e^{W(b; \lambda)} ; \quad (2.87)$$

$W(b; \lambda)$  is the generator of the connected  $\ell$ -point correlators,  $W_{i_1 \dots i_\ell}$ , i.e. the correlators that can be represented as a single diagram, with  $\ell$  open ends:

$$W_{i_1 \dots i_\ell} = \frac{\partial}{\partial b_{i_1}} \dots \frac{\partial}{\partial b_{i_\ell}} W(b; \lambda) \Big|_{b=0} . \quad (2.88)$$

In statistics, the  $W_{i_1 \dots i_\ell}$  are called the *cumulants* of the probability distribution  $e^{-S(x; \lambda)}$ .

# Path Integrals in QM

### 3.1 Path Integrals in Quantum Mechanics

We will introduce Path Integrals in the context of QM. Despite its simplicity all the important features of Path Integrals will be discussed.

Let us denote by  $\hat{Q}$  the position operator, and  $|q\rangle$  the eigenstate corresponding to the eigenvalue  $q$ :

$$\hat{Q}|q\rangle = q|q\rangle . \tag{3.1}$$
